FUNCTION DESCRIPTION

Pin Name	No.	I/O	Description
V _{DD}	1	Power	Input side power supply. A good quality bypassing capacitor is required from this pin to GND and should be placed close to the pins for best results. The under voltage lockout (UVLO) circuit enables the device to operate at power on when a typical supply voltage higher than V _{UVLO1-OUT-ON} is present. Please see Figure 7 for more details.
IN	2	I	Non-inverted gate driver input. The equivalent input pull down resistance is about 100 k Ω when the input voltage is below 5.5 V. The input adapter circuitry will work once the input voltage is higher than 5.5 V, and will keep the input current at the level when the input voltage is 5.5 V even though it is higher than that. A minimum pulse width is required at IN before HO responds.
FLT	3	O	Fault output (active low) that allows communication to the main controller that the driver has encountered a Over Current, or UVLO1, or UVLO2 condition and has deactivated the output. There is an internal 50 k Ω pull-up resistor connected to this pin. Multiple of them from different drivers can be "OR"ed together. /FLT and HO will go high automatically after t _{MUTE} expires along with a rising edge of IN to avoid partial output pulse on HO. This is a feature called "Re-start".
GND	4	Power	Input side ground reference.
V _S	5	Power	Output side ground reference.
CS	6	I/O	Input for detecting over current of IGBT. The current sense threshold has to be met uninterruptedly for a fixed period of t _{FILTER} before HO and /FLT are set low. Please refer to Figure 9 and Figure 10. FLT and HO will be kept low (including soft turn off time) at least for a period defined by t _{MUTE} .
HO	7	O	Driver output that provides the appropriate drive voltage and source/sink current to the IGBT/FET gate. HO is actively pulled low during start-up.
V _B	8	Power	Output side positive power supply. The operating range for this pin is from UVLO2 to its maximum allowed value. A good quality bypassing capacitor is required from this pin to V _S and should be placed close to the pins for best results. The under voltage lockout (UVLO) circuit enables the device to operate at power on when a typical supply voltage higher than V _{UVLO2-OUT-ON} is present. Please see Figure 8 for more details.

Under Voltage Lockout (UVLO)

UVLO ensures correct switching of IGBT connected to the driver output.

- The IGBT is turned-off and the output is disabled, if the supply V_{DD} drops below $V_{UVLO1-OUT-OFF}$ or V_{BS} drops below $V_{UVLO2-OUT-OFF}$.
- The driver output does not follow the input signal on V_{IN} until the V_{DD} / V_{BS} rises above the $V_{UVLOX-OUT-ON}$ and the input signal rising edge is applied to the V_{IN} .

With high loading gate capacitances over 10 nF it is important to follow the decoupling capacitor routing guidelines as shown on Figure 41. The decoupling capacitor value should be at least 10 μ F. Also gate resistor of minimal value of 2 Ω has to be used in order to avoid interference of the high di/dt with internal circuitry (e.g. UVLO2).

After the power-on of the driver there has to be a rising edge applied to the IN in order for the output to start following the inputs. This serves as a protection against producing partial pulses at the output if the V_{DD} or V_B is applied in the middle of the input PWM pulse.

Power Supply (V_{DD} , V_{BS})

NCx57085 is designed to support unipolar power supply.

For reliable high output current the suitable external power capacitors required. Parallel combination of 100 nF + 4,7 μ F ceramic capacitors is optimal for a wide range of applications using IGBT. For reliable driving IGBT modules (containing several parallel IGBT's) a higher capacity required (typically 100 nF + 10 μ F). Capacitors should be as close as possible to the driver's power pins.

Figure 39. Power Supply

Current Sense (CS)

Current sense protection ensures the protection of IGBT at over current. When the V_{CESAT} or V_{SHUTN} voltage goes up and reaches the set limit, the output is driven low and FLT output is activated. To avoid false CS triggering, all CS circuit parts should be placed as close as possible to CS pin and wires from detecting circuit (V_{CESAT} or R_{SHUNT}) should be routed directly and without approaching the power paths.
